Question 1

To create the longest subsequence of elephants, we first sort the elephants in decreasing order of IQs[1,2].

Then, we find the longest increasing subsequence of weight from our collection of sorted elephants.

Let S be our sorted collection, with S_i denoting the ith elephant in the sequence.
Let $W(i)$ be the given weight of elephant i.

Then, for each elephant i in the collection, we let our subproblem be finding a subsequence of maximum length such that $W(i)$ is increasing and the subsequence ends with elephant i.

We do this process recursively, assuming we have solved all the subproblems for some $j < i$, and we look for all elephants m such that $W(m) \leq W(i)$ and $S_m \leq S_i$, picking elephant m which produced the longest increasing subsequence ending with m, and extending it to our subproblem to obtain the longest increasing subsequence ending with elephant i.

Our solution is optimal as truncating the solution i will produce the optimal solution of the subproblem m.

---

[1] Sorting by the weight will also achieve the same result provided the method is inversed.
[2] If two elephants have the same value, we then sort those elephants by the respective inverse of the other value.

Question 2

Let A be the sequence of wooden pieces that will be cut from dividing the wooden stick respective to its marks, with $A[i]$ denoting the size of the ith piece in the sequence.
Let n be the total number of respective pieces.

Let the subproblems to be considered be denoted as $c(i, j)$ and be the minimum of the group of one or more pieces, and the group of the remaining pieces. This group signifies a group to that will be "joined back together", to simulate the cutting cost.

The recursion:

$$c(i, j) = \min \begin{cases} A[i], & \text{if } j = i \\ c(i, k) + c(k + 1, j) & \text{otherwise} \end{cases} : i \leq k \leq j - 1$$

Using this, we then examine every possible way of placing the outermost groupings, which follows from above when $c(0, n-1)$. Doing so will calculate the solutions of all the subproblems, however some will have already been calculated and stored in slots (i, j) of our table.

Since we are examining every possible grouping, our solution is trivially optimal.

Question 3

Let A be a sequence of Roman letters, with $A[i]$ denoting the ith letter of A.
Let B be a sequence of Roman letters, with $B[i]$ denoting the ith letter of B.

Assuming our base cases are solved, we fill our table T, for all $0 \leq a < |A|$ and all $0 \leq b < |B|$ (row by row) as shown in the recursion, where we let a, b be the starting position of strings A, B.

$$s(a, b) = \begin{cases} s(a, b + 1), & \text{if } A[a] \neq B[b] \\ s(a, b + 1) + s(a + 1, b + 1) & \text{if } A[a] = B[b] \end{cases}$$

Finally, the number of sequences found will then be stored in the bottom right of the table, $T[|A|-1][|B|-1]$.

Since we are iterating over every combination of characters, our solution is trivially optimal as truncating the solution will still produce the optimal solution for the previous solution.

Question 4

Let each supervisor be a node.
Let the supervisors' employees' be the node's children.
Let the fun rating of an employee be the node's value.

We then let our subproblem be the maximum of either, the total maximum of a node's children, or total of the node's value and the maximum of each children's children.

We do this process recursively, assuming we have solved all the subproblems for some i. By picking the maximal set of positioned nodes, we are always extending our original subproblem with the largest total value to obtain an increasing total value that must end at the current node.

Thus, our solution is optimal as truncating the solution i will still produce the optimal solution of the subproblem m.

Question 5

Let X, Y be a bit string, where $X[i], Y[i]$ denote the ith bit of the respective string.
Let Z be the interleaved bit string, where $Z[i]$ denotes the ith bit of Z.

Assuming our base cases are solved, we fill our table T, for all $0 \leq a < |X|$ and all $0 \leq b < |Y|$ (row by row) as shown in the recursion, where we let x, y be the starting position of strings X, Y.

$$r(x, y) = \begin{cases} True, & \text{if we've reached the end of all the strings} \\ r(x+1, y), & \text{if } X[x] = Z[x+y] \\ r(x, y+1), & \text{if } Y[y] = Z[x+y] \\ False & \text{otherwise} \end{cases}$$

Finally, solution will then be stored in the bottom right of the table, $T[|X|-1][|Y|-1]$.

Since we are iterating over every combination of characters, our solution is trivially optimal as truncating the solution will still produce the optimal solution for the previous solution.

Question 6

Let our collection of turtles be denoted by T, with T_i denoting the ith turtle.
Let the weight and strength of the turtle T_i be $W(T_i)$ and $S(T_i)$ respectively.

Then for each turtle in T, we let our subproblem be finding the longest chain of turtles such that each turtle's strength is larger than or equal to the total weight of all turtles above it.

However a longest chain may not have the last turtle included as the lowest turtle in the tower, thus our chains cannot be extensions of one another.

Instead we define a new subproblem to find the lightest turtle tower of length l such that no turtles will be cracked, and we define our ordering to use the sum of a turtle's weight and strength, denoted by $W(T_i)+S(T_i)$

We claim that if there exists a tower of length l, then there must exist a tower of the same length such that $W(T_i) + S(T_i) \le W(T_{i+1}) + S(T_{i+1})$ for all $i < l$. By proving this, and showing that the swapping of two adjacent unordered turtles where $W(T_{i+1}) + S(T_{i+1}) \le W(T_i) + S(T_i)$ such that they will preserve our constraints, we can then BubbleSort our stack appropriately.

Assume turtles T_i and T_{i+1} are inverted in our stack such that T_{i+1} is lower in the stack, and $W(T_i) + S(T_i) > W(T_{i+1}) + S(T_{i+1})$, then:

$$\sum_{j=1}^{i} W(T_j) \le S(T_{i+1})$$

Now we add turtle T_{i+1}

$$\sum_{j=1}^{i+1} W(T_j) \le S(T_{i+1}) + W(T_{i+1}) < S(T_i) + W(T_i)$$

Then expand the sum

$$\sum_{j=1}^{i-1} W(T_j) + W(T_i) + W(T_{i+1}) < S(T_i) + W(T_i)$$

Cancelling our the common terms, we then conclude that,

$$\sum_{j=1}^{i-1} W(T_j) + W(T_{i+1}) < S(T_i)$$

such that the left hand side will be what the turtle T_i will see, which is less than $S(T_i)$. Therefore the weight of the turtles above the swapped turtle's is less than it's strength, and thus our turtles will not crack if they are swapped.

Thus, by using the above and building the lightest possible tower of every possible length, we can then obtain a solution for any tower t by picking the longest tower obtained by solving t.
